

# Efficient Querying in Sensor Networks: Flood, Walk, Cache and then ACQUIRE

Presentation for CS428  
-Mukund Sundararajan

# Sensor Networks As Distributed Databases

# Types of Queries in Sensor Networks

- ◆ Continuous queries v/s One shot.
  - Report temperature for next 7 days.
  - Is the current temperature  $>70$ ?
- ◆ Aggregate v/s Non-aggregate.
  - Average temperature of region.
  - What is the temperature measured by node X?
- ◆ Complex v/s Simple.
  - What are the values of vars A,B,C?
  - What is the value of A.
- ◆ Replicated v/s Unique.
  - Is there atleast one node with temp  $>70$ ?

# Approach #1: Flood

- ◆ Query Processing in two phases
  - Sink floods several copies of the query
  - Relevant nodes reply with the answer
- ◆ Energy efficient if continuous query
  - First phase amortizes over many rounds
- ◆ Duplicate responses result in energy losses

# Approach #2: Walk

- ◆ The query performs a guided or random walk in the n/w.
- ◆ Each node partially processes query.
- ◆ Query walks home when solved.
- ◆ Alternatively events may walk.
- ◆ Latency is an issue.

# ACQUIRE

- Published as:
  - N. Sadagopan, B. Krishnamachari, A. Helmy, "[The ACQUIRE Mechanism for Efficient Querying in Sensor Networks](#)", *First IEEE International Workshop on Sensor Network Protocols and Applications (SNPA), in conjunction with IEEE ICC 2003*, pp. 149-155, May 2003, Anchorage, AK, USA.
  - ACTive QUery forwardIng in sensoR nEtworks.
  - Simple 7 page paper.
- **Contributions.**
  - Query processing protocol : ACQUIRE.
  - Modeling and analysis of energy consumption.
  - Comparison with other protocols.

# Central Idea

- ◆ Study trade-off between Walk and Flood approaches
- ◆ Use intelligent caching
- ◆ Good for one-shot, complex, replicated non-aggregated queries
  - Obtain sample calls for Blue-jays, Nightingale, Cardinal and Warbler

# Data Tracking and Query Model

- ◆ Let  $V = \{V_1, V_2 \dots V_n\}$  be  $n$  variables.
- ◆ Let  $Q = \{Q_1, Q_2 \dots Q_m\}$  be the query.
- ◆ Each node keeps track of one variable with uniform random probability.
- ◆ Query is issued at node  $x^*$ .
- ◆ Assumption that there is data replication:  $N/M$  nodes have partial answer to a query.

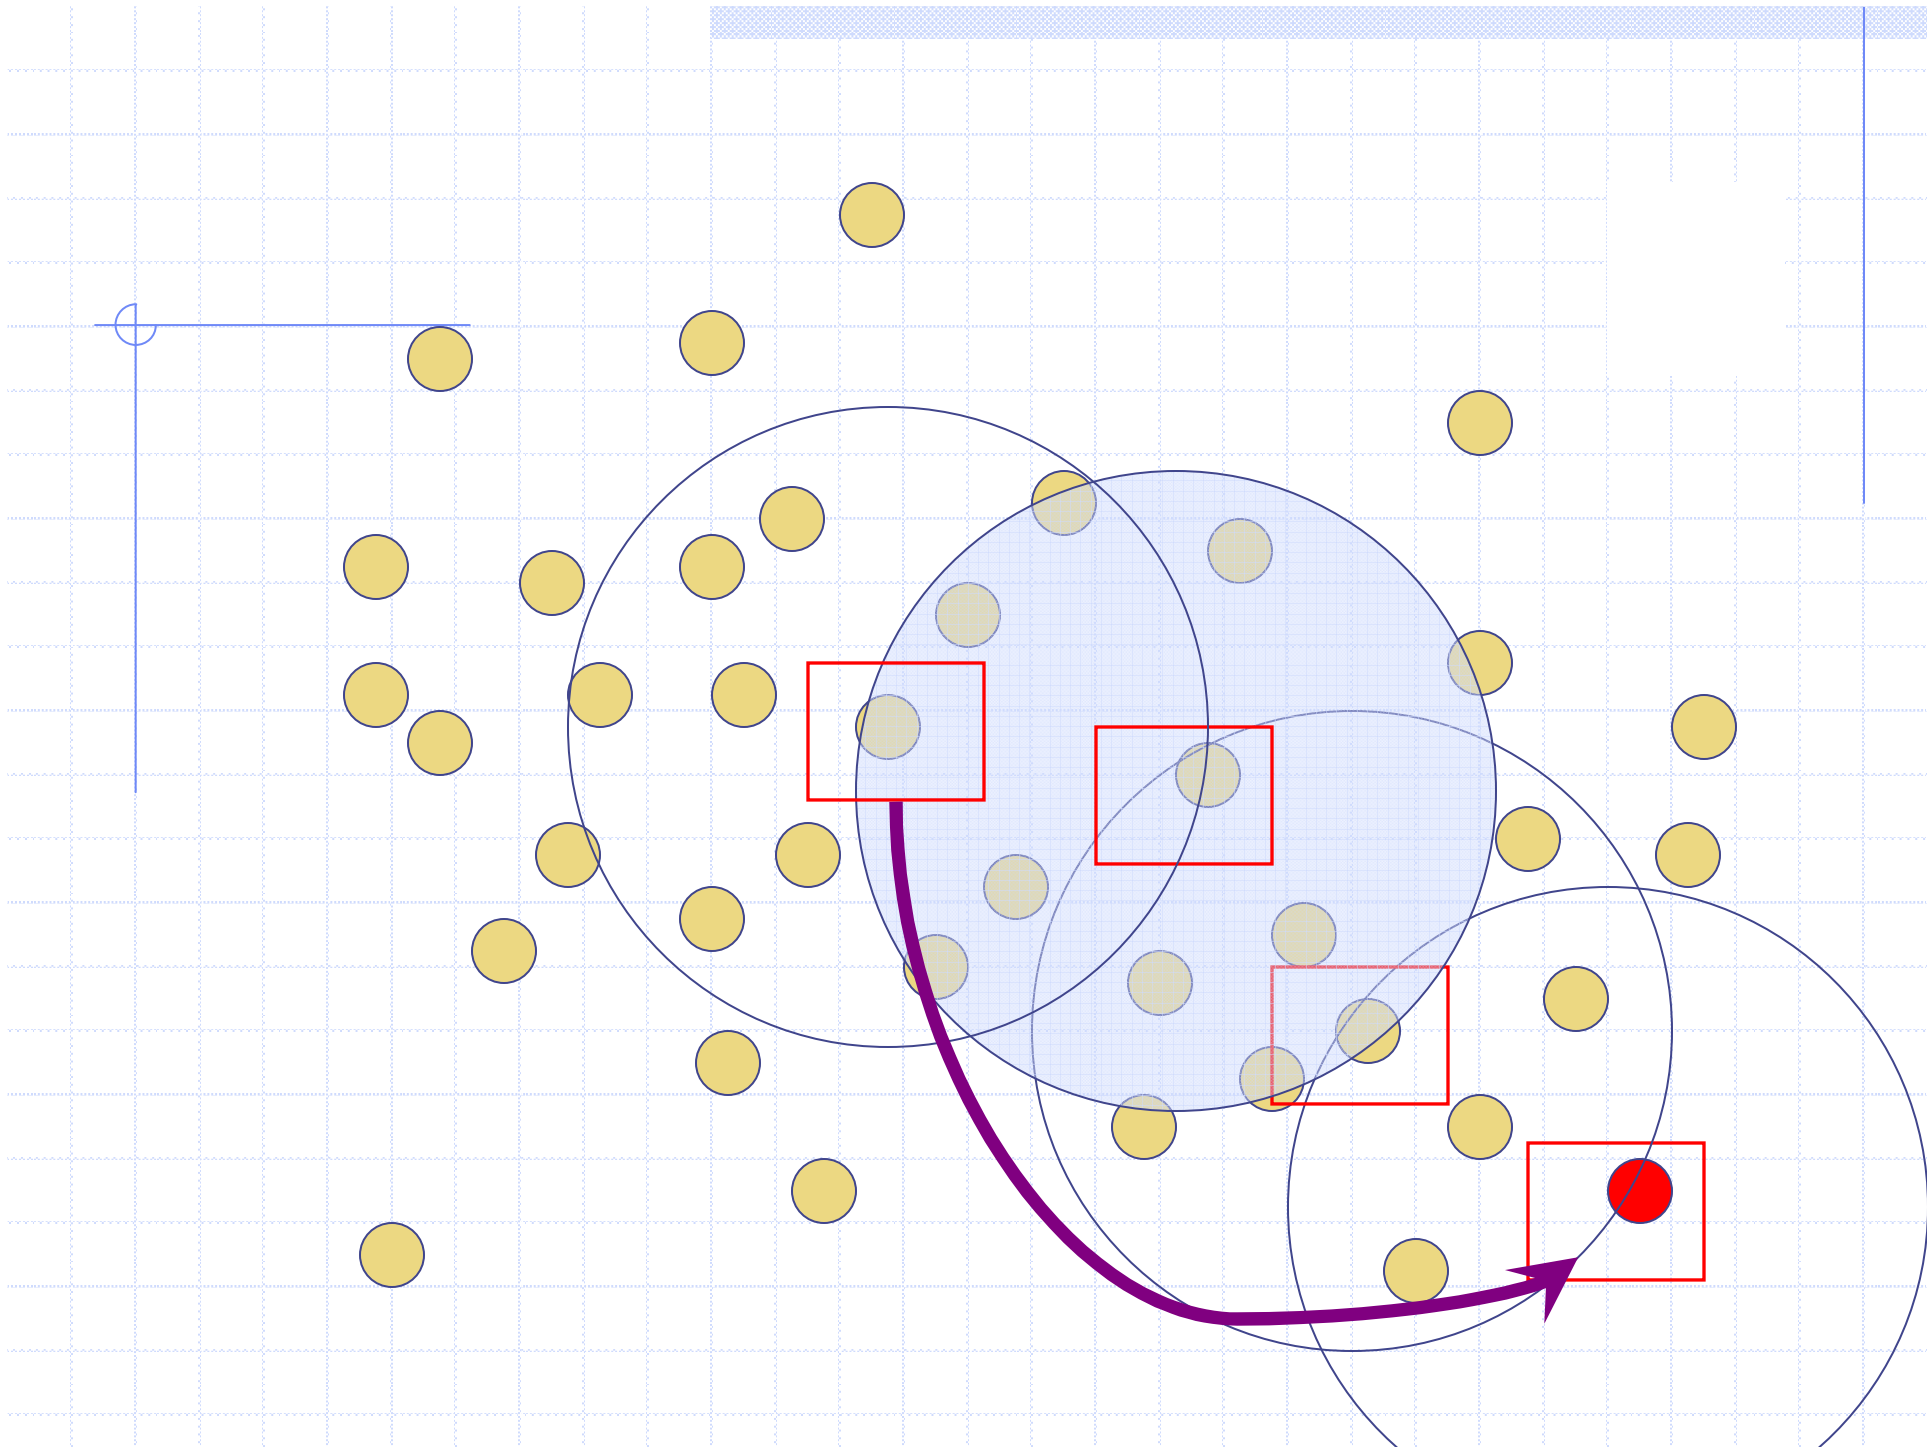

# ACQUIRE Preliminaries

- ◆ Each active node maintains information about nodes within  $d$  hops.
- ◆ The number of such nodes is given by the n/w topology dependant function  $f(d)$ .

# ACQUIRE Mechanism

- ◆ A random walk is performed starting at  $x^*$ .
- ◆ Current node may refresh data from neighbourhood.
- ◆ Query is resolved based on partial information
- ◆ The query is then forwarded to a random node at the edge of its neighbourhood

# How Much Energy Is Consumed ?

Energy is measured in terms of number of transmissions

# Energy Analysis: Notation

- ◆ Let  $V = \{V_1, V_2 \dots V_n\}$  be  $n$  variables.
- ◆ Let  $Q = \{Q_1, Q_2 \dots Q_m\}$  be the query.
  - $m < n, Q_i \in V.$
- ◆  $S_m$  be the average number of steps.
- ◆  $d$  is look-around of an active node.
- ◆  $f(d)$  be the number of nodes within  $d$  hops.
- ◆  $c$  is update frequency.

# Energy Analysis Equation

◆ 
$$E_{avg} = (cE_{update} + d)S_m + \alpha \quad (1)$$

◆ alpha is average distance to sink

◆ Note special cases

■ If  $d = \text{Diameter}$  then Flooding

■ If  $d = 0$  then Random walk

◆  $S_m$  reduces as  $d$  increases

# Energy Analysis: Estimating Expected Number of Steps: $S_m$

- ◆ Suppose each node tracks a single  $V_i$  with equal probability
- ◆ Estimate number of hops with  $d=0$ . (Random Walk )
- ◆ Given a query  $Q$ , consider a trial which asks if a particular node can satisfy any variable in the query
- ◆ Success probability:  $M/N$
- ◆ In a random walk, expected time to first success is  $N/M$

# Estimating $S_m$ Contd...

$$E(\sigma_M) = N \sum_{i=1}^M \frac{1}{M - i + 1} = NH(M) \quad (2)$$

$$E(\sigma_M) \approx N(\ln M + \gamma) \quad (3)$$

$$S_M = \frac{E(\sigma_M)}{f(d)} \approx \frac{N(\ln M + \gamma)}{f(d)} \quad (4)$$

Increasing  
look-around  
reduces walk  
length

# Estimating Energy for a Triggered Update

$$E_{\text{update}} = (f(d - 1) + \sum_{i=1}^d iN(i)) \quad (5)$$

- ◆  $N(i)$  is the number of nodes at distance  $i$ .

# Total Energy Consumed ( in a Grid )

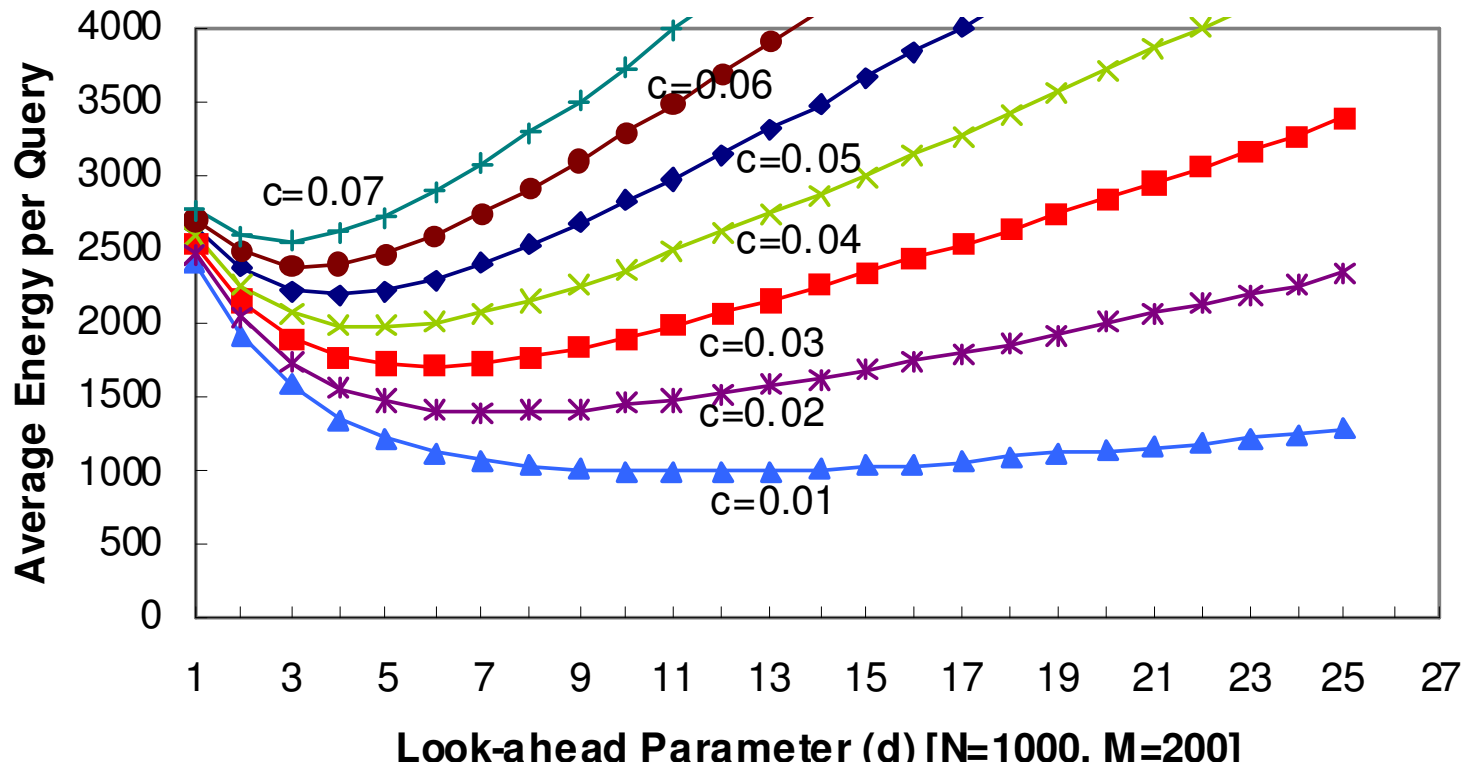

$$E_{avg} \approx \left\{ \frac{cN(\ln M + \gamma)}{3} \frac{4d^3 + 12d^2 - 4d + 3}{2d^2 + 2d + 1} + N(\ln M + \gamma) \frac{2d}{2d^2 + 2d + 1} \right\} \quad (9)$$

- ◆  $N(i) = 4i$  for a grid (ignoring boundary)
- ◆  $f(d) = 2d(d+1) + 1$
- ◆ Gamma is Euler constant
- ◆ To find the optimal  $d^*$ , differentiate wrt  $d$ . and set to 0.

# Energy Consumed.

$d^*$  is larger for smaller values of  $c$

## Performance of ACQUIRE

# Flood Based Approach.

- ◆ Flood Query
- ◆ All nodes that track the variables respond
- ◆ Use the caching idea

$$\begin{aligned} E_{avg} &= (f(R) + \sum_{i=1}^R i N_{avg}(i))c \\ &= (f(R) + \frac{M}{N} \sum_{i=1}^R i N(i))c \end{aligned}$$

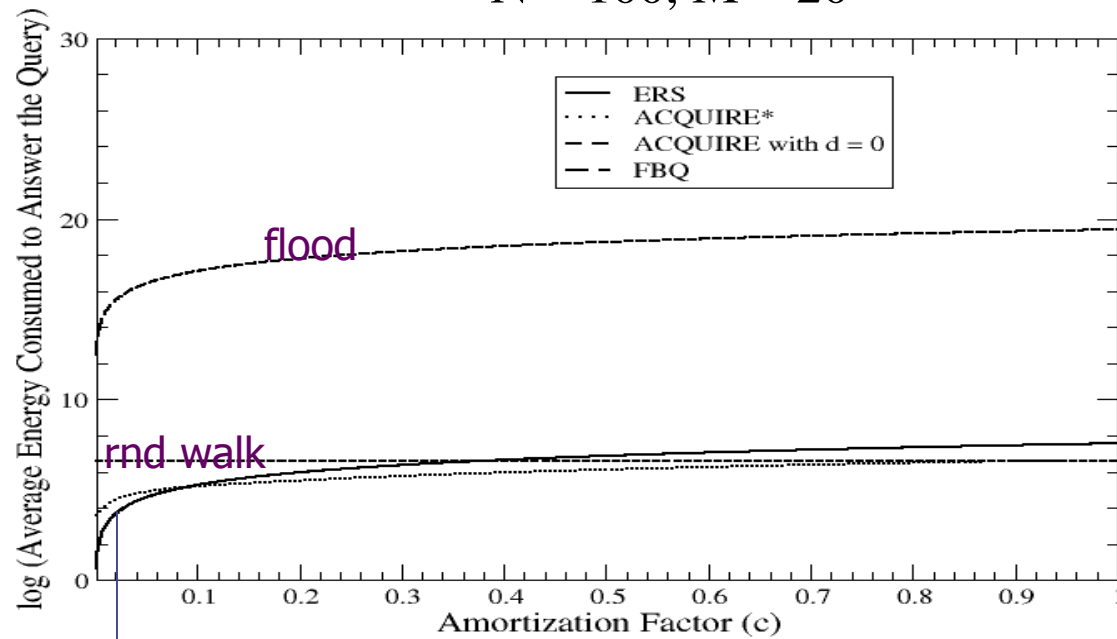

- ◆  $E_{avg}$  proportional to  $X^{3/2}$
- ◆  $X$  is the number of nodes in the n/w.

# Expanding Ring Search

- ◆  $d=0$  at Start.
- ◆ The query node  $x^*$  tries to answer query  $Q$  using updates from nodes within distance  $d$ .
- ◆ If query is not satisfied,  $d$  is increased by 1.
- ◆ Use the caching idea.
- ◆ Similar equations, see paper.

# Comparison

$N = 100, M = 20$

ACQUIRE\* has a 60 % improvement over ERS

Expanding ring search

For this case, Acquire\* outperforms ERS if  $d^* \leq 1$

# Notes

- ◆ Efficiency can be improved by guiding trajectory
  - Reducing overlap
  - Guiding query towards regions of information
- ◆ Find value of the look-around  $d$  based on the amortization factor  $c$ ; this factor is application dependant
- ◆ Nodes could take turns being active

# Take Home Message

- ◆ Query processing in sensor n/w depends on:
  - Nature of query
  - Data Replication impacts efficacy of walks
  - Rate of change of data values impacts efficacy of caching
  - Topology of the network

**ONE SIZE DOES NOT FIT ALL!**
