## Flipping

Peeking underneath at Roomba's private parts, we can see what makes the Roomba go—and how it decides to stop. The Roomba uses two drive wheels with sturdy treads, and a third caster wheel for stability, allowing it to zip around and maneuver curvy paths and tight corners. Infrared cliff sensors and bump contact sensors give Roomba some awareness. They warn Roomba if it is approaching a step or if it has bumped into something so it can avoid serious falls and collisions. (See "The Brawn" and "The Brains" for more details about the wheels and sensors.)

## Unclipping

Roomba's modular design makes part replacement and cleaning easy. Its battery, brushes, dustbin and vacuum motor are all removable. Behind the dustbin, we can see Roomba's two dirt sensors above the agitator brush; these are piezo-acoustic sensors that measure the number of dirt particles being picked up, enabling the Roomba to increase the intensity of the vacuuming where it is needed, and to determine when the room is clean enough to stop.

## Stripping

As we dig deeper, we see the chassis includes four side brushes that help with interesting to note the mirrored on the left. clockwise circles, and

## The Brawn

The Roomba's drive system is more sophisticated than the simple direct current (DC) motors you find in remote-controlled cars. DC motors are part of the powertrain, but each motor unit also houses an optical encoder which measures how fast and how far each wheel is moving. In the picture above, the red and yellow wire strands provide power to the motors, while the other wire bundle feeds the encoder output to the odometer.

The DC motor is connected to the wheel via a belt drive, which offers a little safety in case the Roomba gets stuck: it will wear out before destroying whatever it's stuck on. The spoked wheel is used as an optical interrupter that alternately blocks and allows IR light from an LED to reach a photodetector. Each pulse of light between the spokes is another few millimeters of movement. Optical interrupters like this are also used in ball-type computer mice.

Inside each Roomba wheel is a sealed planetary gear system that converts the high speed, low torque DC motor output into high torque, low speed movement. Torque output is sufficient to carry about two gallons of house paint on a Roomba without problems.

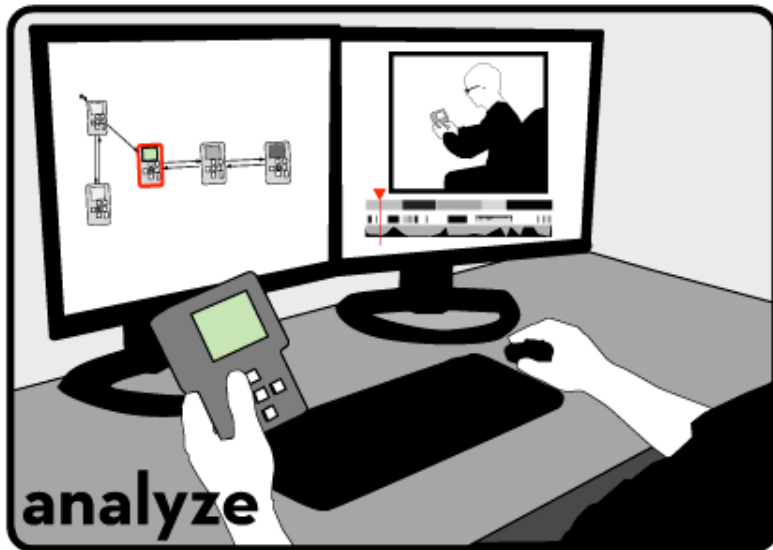

## The Brains

Connectors converge on the main processor's circuit board.

All sensor and actuator cables of the Roomba converge on the main processor's circuit board. The board is easily serviced, with soldering wires directly to the board, a variety of adhesives (except for some hot-glue tape) and a 6MHz, 16bit Motorola microcontroller. The board reads sensor data 67 times per second to process algorithms based on MIT professor Rodney Brooks' navigation system.

Run Add Alternative Linked Edit

Alternative 1 Alternative 2

int ledPin = 2;
int dly = 25;
boolean blink=false;

void setup() // run once, when the sketch starts
{
  pinMode(ledPin, OUTPUT); // sets the digital pin as output
  digitalWrite(ledPin, HIGH); // sets the LED on
}

void loop() // run over and over again
{
  if(blink) {
    digitalWrite(ledPin, LOW);
    delay(dly);
    digitalWrite(ledPin, HIGH);
    delay(dly);
  }
}
```

The image shows a screenshot of an IDE window with a menu bar (File, Edit, Run, User Study) and a toolbar containing 'Run', 'Add Alternative', and 'Linked Edit' (checked). Below the toolbar are two tabs: 'Alternative 1' and 'Alternative 2', with 'Alternative 2' selected and highlighted by a red box. The main text area contains C++ code for a sketch with two LEDs. The code is as follows:

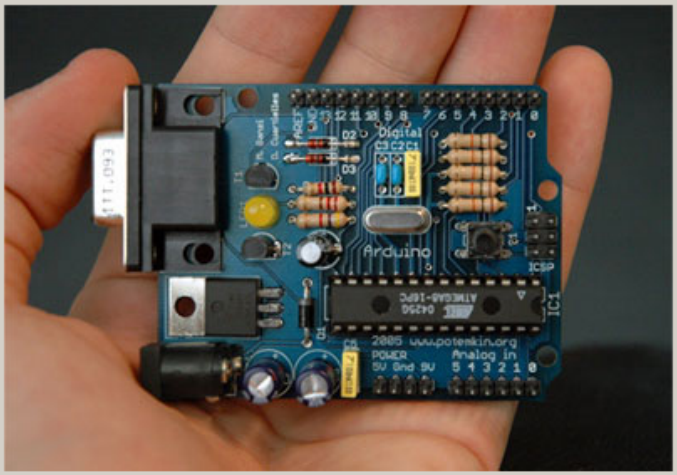

```
int ledPin = 2;
int dly = 25;
boolean blink=false;
int ledPin2 = 3;

void setup()           // run once, when the sketch starts
{
  pinMode(ledPin, OUTPUT);    // sets the digital pin as output
  pinMode(ledPin2, OUTPUT);  // sets the digital pin as output
  digitalWrite(ledPin, HIGH); // sets the LED on
}

void loop()           // run over and over again
{
  if(blink) {
    digitalWrite(ledPin, LOW);
    digitalWrite(ledPin2, LOW);
    delay(dly);
    digitalWrite(ledPin, HIGH);
    digitalWrite(ledPin2, HIGH);
    delay(dly);
  }
}
```

**Alternative2.hex**

**Bootloader**

# Tradeoffs

- What you gain:
  - Tuning “on the fly”
  - Relatively little overhead
- What you lose:
  - Use of a hardware serial port

**Mini Talk #2 (not research):  
No more zombie prototypes!**

**Write code here**

**Store source here**

**Run code here**

**Store binaries here**

**What could possibly  
go wrong?**

- My dog ate the laptop
- My files are a total mess
- Uhm, that was 3 years ago...
- Oops, forgot that at \_\_\_\_\_

**How \$8 can save the day...**

**PC/MAC**

**Microcontroller**

**PC/MAC**

**Microcontroller**

**Storage**

*All sources stay here*

**PC/MAC**

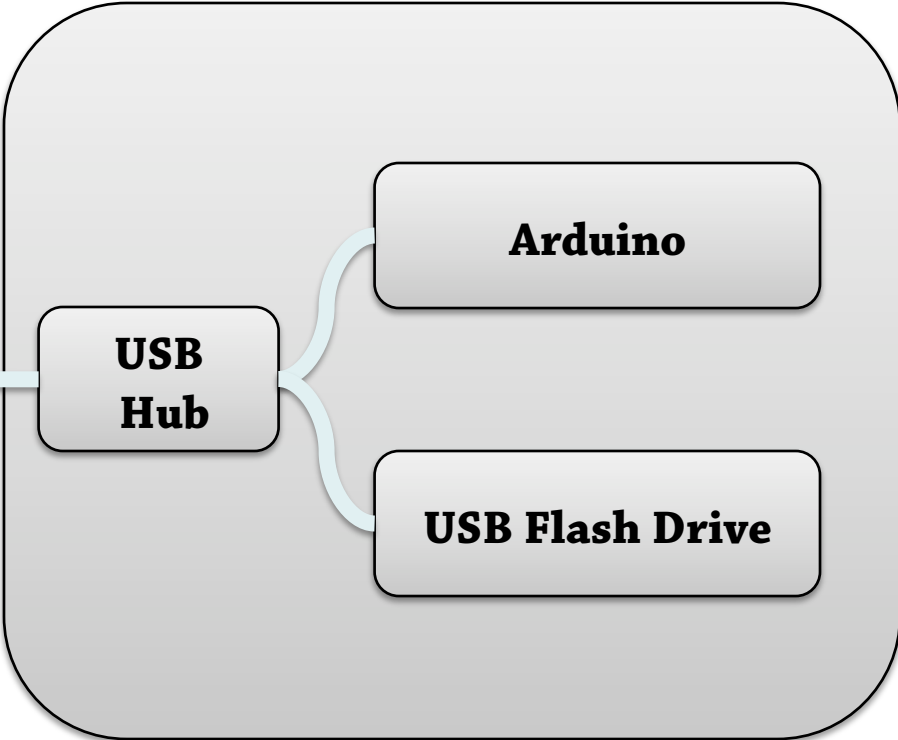

**USB  
Hub**

**Arduino**

**USB Flash Drive**

# Observations

- This can obviously be miniaturized.
- Upgrade the hardware (256MB,USB2.0) and run entire development environment directly off the stick
- Where should storage ideally be located?  
On a shield? Or on the board itself?

## Final requests:

- Good design process examples (products & end-user modifications).  
The prototypes and discussion that went into them, alternatives tried, etc.
- Know of any open academic jobs?
